Abstract

High Intensity Focused Ultrasound (HIFU) is a non-invasive ablation technique that has created massive interest in clinical applications such as hyperthermia and thermal therapy. HIFU generates heat at the target region, however, temperature monitoring is essential to avoid damaging healthy tissues in the heated region. Although Magnetic Resonance Imaging (MRI) does provide highly accurate temperature monitoring, ultrasound imaging transducer is more advantageous in temperature estimation due to its portability, low costs, and non-ionizing radiation.

Using the physical properties of ultrasound waves, many studies have been conducted for thermal monitoring using HIFU. These classical methods have an unavoidable trade-off between image quality and computational speed. The last decade has seen a significant boost in deep learning and neural networks for all applications due to its high performance while being computationally efficient. We propose to employ a more recent type of neural network, namely a Generative Adversarial Network (GAN), to perform ultrasound temperature estimation.

A MATLAB-based HIFU simulator was used to generate the intensity and the corresponding temperature maps for four different tissue combinations, which were used as input data for the GAN. The capabilities of GAN has made it a state-of-the-art neural network for tasks such as image generation, classification and segmentation. This thesis demonstrates the use of GAN in temperature map estimation of the tissue in the region of interest. The promising results show the feasibility of using GAN in clinical-based applications.

Acknowledgements

I want to thank Dr. Mohamed Almekkawy for his continuous support and expertise in ultrasound imaging and neural networks. When I started to work with Dr. Almekkawy, I was very unaware of the field of ultrasound imaging and its scope. By starting with literature reviews of some of the well-known researchers in the field, I was able to get a better understanding of the field and have a much more knowledgeable conversation with Dr. Almekkawy every week as we spoke and discussed the possibilities for my thesis. From constructing my data set to building a neural network with Pytorch, I have gained a wealth of experience from this project. For my future endeavors, I feel confident in my ability to step out of my comfort zone and solve complex problems.

I would also like to thank my honors advisor, Dr. Robert Collins, for his tremendous support over my four years as an undergraduate. From my academics to my research, his advice and friendly conversations have been instrumental to my success so far. I would also like to thank Sahil Ahmed for his continuous support in building the generative adversarial network. Lastly, I would like to thank my friends and family for encouraging me through difficult times in this project.

Chapter 1

Introduction

Over the past few decades, with the rise of high-performance computers, medical imaging has become an essential clinical trial tool. Medical imaging allows for a visual representation of organs and tissues, which helps detect abnormalities and their treatment. Standard imaging technologies include X-ray, Computer Tomography (CT), Ultrasound, and Magnetic Resonance Imaging (MRI). An example of some of the medical imaging techniques mentioned is given in Figure 1.1. The topic of medical imaging is so vast that over 5 billion studies have been conducted in the field as of 2010 [1].

Although these conventional techniques may be definitive and decisive, there are shortcomings. For instance, MRI provides incredible image quality, but it is very expensive and takes a more considerable amount of time to provide results. It even cannot always find all cancers [2]. With the case of X-ray, it is not as expensive as MRI and is much more easily portable and accessible but requires a wealth of experience to identify inconsistencies in the regions of interest correctly.

The use of ultrasound can offer relative solutions to some of the problems faced by other medical imaging techniques. Ultrasound offers a relatively lower cost, is easily portable, accessible, and provides incredible image quality with low ion radiation. The rise in studies of ultrasound usage for therapeutic applications has been encouraging, even though ultrasound imaging was seen in the past to produce blurry images. The non-invasive nature of ultrasound imaging also promotes its therapeutic applications. A sonogram of a fetus is shown in Figure 1.2.

Thermography is generally defined as recording surface temperature changes. However, in medical imaging, it refers to the qualitative non-invasive imaging of tissue temperature change using any of the techniques mentioned above [3]. An example of the thermal map of the human upper body is shown in Figure 1.3. It is a continuously explored field in medical imaging because it can provide the tools for evaluating and monitoring real-time tissue temperature change. This could be crucial for the future of cancer thermotherapy, and with proper clinical trials, it could be groundbreaking.

1.1 High-intensity focused ultrasound

To continue the focus on ultrasound imaging, high-intensity focused ultrasound has allowed for non-invasive tissue heating and ablation applications. The goal of most cancer therapies is to destroy cancerous cells while keeping nearby healthy cells unaffected selectively. The role of high-intensity focused ultrasound (HIFU) is to increase the temperature around an isolated tissue for a period of time which would lead to necrosis and cell death [4]. HIFU works by using sound energy to create heat around a specific region. Ultrasound waves of short wavelength and high frequency carry energy, which increases the temperature around a region of focus. The volume of destroyed cells is called a lesion and is where the ultrasound waves are focused. The representation in Figure 1.4 shows a simple HIFU setup with its region of focus.

Figure 1.4: Illustration of HIFU setup with a transducer emitting ultrasound waves which are focused on a region in the tissue for lesion generation.

Taken from [4]

Ultrasound waves are created by the vibrating of a piezoelectric (electricity resulting from pressure) material, which is the HIFU transducer's role. The piezoelectric transducer converts an oscillating signal into an acoustic wave and vice versa. The transducer, also known as a probe, can be of phased array, curvilinear or linear array with multiple frequencies in one probe. The higher number of frequencies in the probe, the better the resolution of the image. The transducer also receives the ultrasound waves and converts them into electrical signals for processing and display.

In the interest of non-invasive temperature estimation, multiple research groups have investigated the application of magnetic resonance imaging, impedance tomography, microwave radiometry, and backscattered ultrasound [5]. Every technique has its pros and cons; the main reasons to investigate further with ultrasound are its low cost, portability, and real-time data collection. Many factors and approaches have been suggested over the past few decades, from the analysis of frequency-dependent attenuation [6], backscattered power [7], speed of sound and thermal expansion [8]. After a region of the tissue is heated, the backscattered ultrasound waves are RF-echoes that experience time shifts caused by thermally induced local changes in the speed of sound. In [8], temperature estimation was performed along one dimension by tracking the frequency variation of the echo components in the spectral domain, whereas in [5] the temperature was estimated along two dimensions using a separable two-dimensional finite impulse response (FIR) filter. In the study of [9] - [10], the algorithm for temperature estimation is based on tracking the echo time shifts in the time domain. The time-shift estimates are then differentiated along the axial direction to obtain one-dimension temperature estimates. These classical methods have laid a foundation for advanced and modern techniques such as computer-based simulations and soft-computing methods [11].

1.2 Neural Networks in Medical Imaging

The rise of machine learning and artificial intelligence over the past decade or so has opened up so many different applications and fields with the use of high-performance computing. Taking inspiration from how the human brain performs a task or function by sending signals across billions of neurons resulted in the concept of artificial neural networks. A simple network such as the one in Figure 1.5, consists of the input layer, hidden layer(s), and output layer. The connection between each layer is called a link, and every link is weighted. To know which neuron should output an on/off or high/low, an activation function (usually non-linear) is applied to the input signal and determines the corresponding output signal. The method of determining the weights on the links is the key area of research, as many algorithms have been devised for the so-called training of the network. Training the network on seen data and then testing on unseen data to make a prediction is fundamental for machine learning.

In the field of medical imaging, many studies have been conducted on how to incorporate artificial neural networks to perform the task of temperature estimation. The most common types of neural networks used for thermal imaging reconstruction include convolutional neural networks (CNN) [12] and radial-basis function neural networks (RBFNN) [11]. An example of such a network is shown in Figure 1.6. These studies have produced encouraging results and show the scope of the usage of artificial neural networks for the purpose of medical imaging.

Figure 1.5: Simple artificial neural network with one hidden layer

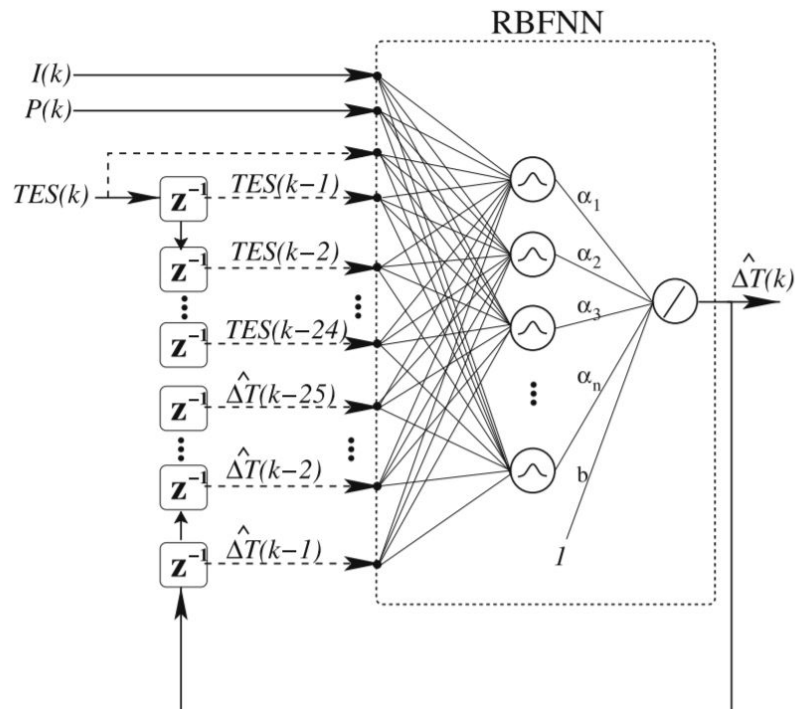

Figure 1.6: Use of a radial-basis function neural network where temporal echo shifts (TES) and change in temperature ΔT from 25 previous time steps along with intensity and pressure values at time k are used as inputs to predict the temperature at time k .

Taken from [11]

Generative adversarial networks founded in 2014 by Ian Goodfellow [13] have become the latest key topic of interest in the field of machine learning and artificial intelligence. There are two networks competing against each other, hence the name adversarial, to generate a so-called fake image based on the training data presented. The simplest version of this network is called a vanilla GAN, containing a single generator and discriminator to create a fake sample. Many variations have been discovered and tested, such as BiGAN, InfoGAN, ACGAN, CGAN, and many more. In medical imaging, the review by Yi, Walia, and Babyn [14] provides excellent detail into the various types of GANs being studied and implemented for tasks such as image synthesis, reconstruction, segmentation, classification, detection, registration, and many other possible applications.

For the purpose of ultrasound temperature estimation, a GAN with a single generator and discriminator is being used. Intensity maps produced for multiple tissue combinations are used as input training data, and temperature maps are used as the ground truth. This novel approach of using a GAN for the purpose of ultrasound temperature estimation is studied and discussed in the following chapters.

Chapter 2

Methods

In this chapter, a detailed analysis is provided of the theory and methods behind the generation of the data set and the architecture of the generative adversarial network being used. The non-linear effects in a typical ultrasound beam are due to the diffraction phenomena and the finite amplitude effects, which vary from point to point within the beam [15]. Due to the non-linear characteristics of the ultrasound wave, we need an equation to provide the solution which models the non-linear acoustics. The Khokhlov-Zabolotskaya-Kuznetsov (KZK) equation serves as a tool to solve non-linear acoustics and is a key driver in the data set generated from the HIFU simulator.

The thermal model consists of the Pennes bio-heat transfer equation, which governs the thermal effects in a tissue. It provides an analytical solution for the temperature variation in the tissues in the time domain. Since ultrasound waves carry energy and heat a region of focus, the solution to the bio-heat transfer equation using Laplacian transformations can predict the temperature profile of the tissue. These two models, acoustic and thermal, help in generating the intensity and temperature maps for the respective tissue combinations from the HIFU simulator.

Neural networks play a significant role in the actual ultrasound temperature estimation. A generative adversarial network is being used to perform the task. It consists of a generator and a discriminator, which are essentially competing against one another to produce the best model for the required task. The architecture of the two models is discussed in detail, along with the activation function and optimizations used.

2.1 The KZK Equation

In theory, ultrasound waves induce a change in pressure as it propagates through a medium. This results in non-linear characteristics of the wave. The Khokhlov-Zabolotskaya-Kuznetsov (KZK) equation provides a finite difference solution for a non-linear wave equation [15]. When the transducer lies in the (x, y) plane normal to the direction of beam propagation which would correspond to the z axis, the KZK equation is written as shown in Eq. 2.1

$$\frac{\partial^2 p}{\partial z \partial \tau} = \frac{c_0}{2} \nabla_{\perp}^2 p + \frac{\delta}{2c_0^2} \frac{\partial^3 p}{\partial \tau^3} + \frac{\beta}{2\rho_0 c_0^3} \frac{\partial^2 p^2}{\partial \tau^2} \quad (2.1)$$

where p is the sound pressure, c_0 is the small-signal sound speed, δ is the sound diffusivity, β is the non-linearity constant, ρ_0 is the ambient density, τ is the retarded time and ∇_{\perp}^2 is the Laplacian operator in the (x, y) plane [16].

Using the HIFU simulator described in [17], a data set comprised of intensity maps, heat maps and temperature maps for 4 different combinations of various tissues was created in MATLAB. The various KZK parameters such as small-signal sound speed c , mass density ρ , absorption at 1MHz α , exponent of absorption vs. frequency curve η , non-linear parameter β and material transition distance z were set for each material pair combination. The axysymmetric KZK equation is then intergated in the frequency domain to produce the axial and radial pressure amplitude, intensity and heating rate.

2.2 The bio-heat transfer equation

To determine temperature and thermal effects in a tissue, the bio-heat transfer equation is used as shown in Eq. 2.2 [18], [19]

$$\rho C_t \frac{\partial T}{\partial t} = k \nabla^2 T - W_b C_b (T - T_b) + Q \quad (2.2)$$

where the parameters T , T_b , ρ , C_t , C_b , k , Q , and W_b are the tissue temperature, arterial blood temperature, tissue density, specific heat of tissue, specific heat of blood, thermal conductivity of the tissue, applied transducer intensity and perfusion constant respectively.

The HIFU simulator uses the axial and radial pressure amplitude, intensity and heating rate from integrating the axysymmetric KZK equation as a source for the bio-heat transfer equation. The BHT solver also uses certain parameters of the material being used, namely heat capacity C , thermal conductivity k and perfusion rate w . The baseline temperature T_0 used is $37^\circ C$. The simulator then integrates and solves the bio-heat transfer equation providing the spatial temperature distribution and thermal dose.

2.3 Generative adversarial networks

For the purpose of ultrasound temperature estimation, a deep learning approach is taken by using a Generative Adversarial Network (GAN) [13]. The general network architecture primarily

consists of a generator G and a discriminator D . The generator takes in an input sample and generates new examples whereas the discriminator acts as a classifier between a real example and the fake generated example. The main objective of the generator is to obtain a higher probability of fooling the discriminator with the fake sample it generated. In ultrasound temperature estimation, this translates to the generator training on multiple intensity maps and providing a fake temperature map such that it can fool the ground truth temperature map which the discriminator possesses. Figure 2.1 gives a representation into the adversarial system.

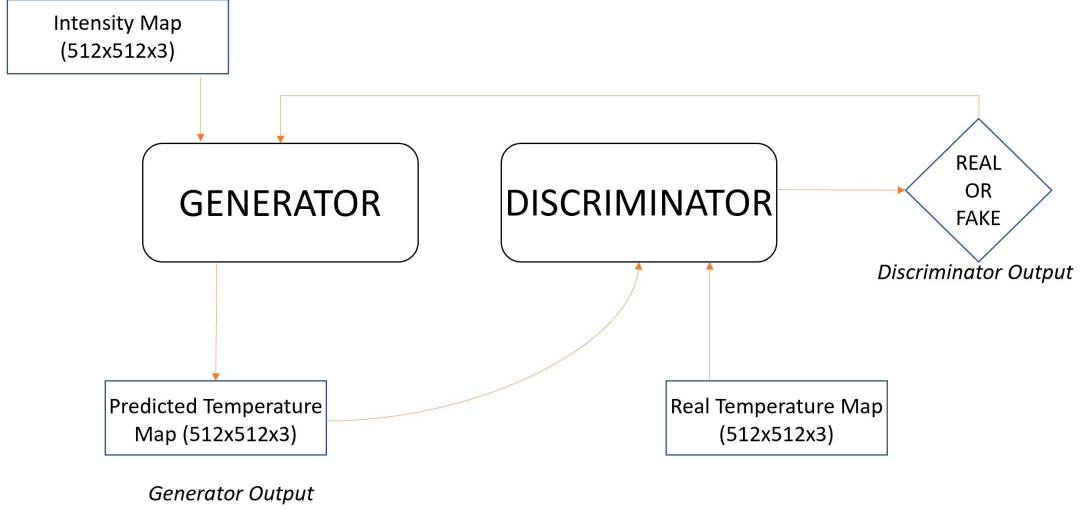

Figure 2.1: Generative adversarial network block diagram for the purpose of ultrasound temperature estimation.

As mentioned in [13], it is the discriminator who is left to always guess at 50% confidence as to whether or not the generator output is real or fake. In mathematical terms, let x be the input training sample i.e. the intensity map with $D(x)$ as the discriminator output which represents the probability of whether the predicted temperature map is from the ground truth or not. For the generator let z be the latent space vector with $G(z)$ representing the generator function which maps the latent vector z to data-space.

The generator output (p_g) being the probability of producing an output temperature map that makes the discriminator believe that the prediction is from the ground truth (p_{data}). From this we can say that $D(G(z))$ is the probability that a real temperature map is produced by the generator.

Goodfellow [13] also mentions that D and G are playing a minimax game where D is trying to maximize its probability of correctly classifying between real and fake samples ($\log(D(x))$) and concurrently G tries to minimize the probability of D correctly identifying a fake sample from a real sample ($\log(1 - D(G(x)))$).

The GAN loss function from the paper can be described as mentioned in Eq. 2.3.

$$\min_G \max_D V(D, G) = \mathbb{E}_{x \sim p_{data}(x)} [\log(D(x))] + \mathbb{E}_{z \sim p_z(z)} [\log(1 - D(G(z)))] \quad (2.3)$$

Ideally, the solution to the minimax game would be when $p_g = p_{data}$ and the discriminator will be guessing a real or fake with 50% confidence i.e. $D(x) = \frac{1}{2}$.

The architecture followed by both generator and discriminator is still a key research area as the best architectures are still being determined. Generally, a mix of convolutional layers, batch normalization and non-linear activation functions are used.

The generator model for ultrasound temperature estimation is inspired by the U-net architecture as described in [20]. The model contains a contracting path and an expansive path which gives the network its U-shape. For down sampling 8 two-dimensional convolutional layers with batch normalization and leaky ReLU activation function are used. For up sampling 7 two-dimensional convolution-transposed layers with batch normalization, ReLU activation function and dropout on certain layers are used. A final convolutional layer to maintain the $512 \times 512 \times 3$ size is also used. In total 16 convolutional layers are used in the generator network. The network architecture is shown in Figure 2.2.

The discriminator model performs the task of binary classification and requires two-dimensional convolutional layers with batch normalization and leaky ReLU activation function. 6 such layers are used in the discriminator. A total of 22 convolutional layers are used in the entire generative adversarial network.

Figure 2.2: U-net architecture for the generator model where each blue box represents a convolution with the various colored arrow keys indicating up-down sampling. The size of the image after each layer is mentioned on left side of each blue box with the number of channels above every box. The output image represents a 3-channel map since our image is $512 \times 512 \times 3$.

Chapter 3

Numerical Simulations

In this chapter, the numerical simulations are provided with the tissue combinations and respective parameters for the data set generated from the HIFU simulator followed by the postprocessing before being used as training and testing data for the generative adversarial network.

The HIFU simulator was run on MATLAB due to its ease of use with handling large matrices, image processing, and portability. The mathematical calculations involved in solving the KZK and bio-heat transfer equation were highly optimized in MATLAB as well. Once the full intensity and temperature matrices were generated from the axisymmetric KZK and axisymmetric BHT solver respectively, the scaled colored maps of the matrices were generated using the `imagesc` method. These correspond to the intensity and temperature maps for a tissue pair combination.

For the generative adversarial network, the open-source machine learning library of PyTorch was used for implementing the neural network. Python is one of the world's most popular languages, allows for seamless integration and use of a vast array of libraries. The NumPy library went hand-in-hand with PyTorch and allowed for the use of the MATLAB-generated data set to be incorporated as the input data. PyTorch also allows for data parallelism, where the computational work can be distributed amongst the CPU or GPU cores. With the easy enabling of CUDA, the network performed computations at a rapid rate on the GPU.

3.1 Data set Generation

The HIFU simulator described in [17] is used for the generation of 1000 intensity and temperature maps for 4 combinations of tissues. While performing the integration of the axysymmetric KZK equation the parameters in Table 3.1 are fixed for the transducer and computational domain.

Table 3.1: Fixed KZK Parameters

	Parameter	symbol	value	unit
Transducer	outer radius	a	2.5	cm
	inner radius	b	1	cm
	focusing depth	d	8	cm
Computational Domain	max radius	R	a	cm
	max axial distance	Z	$1.5d$	cm
	number of harmonics	K	128	–
	material transition distance	z	5	cm

For the generation of the data set, the frequency is swung from 300 KHz to 3 MHz in increments of 100 KHz and the power is swung from 80 W to 500 W in increments of 20 W.

For the bio-heat transfer equation solver, the sonication sequence parameters described in Table 3.2 are fixed as well.

Table 3.2: Fixed Sonication Parameters

	Parameter	symbol	value	unit
Sonication Sequence	initial sonication duration	t_i	0.3	sec
	number of additional pulse cycles	n_c	5	–
	duty factor	D	20	%
	pulse cycle period	t_p	0.5	sec
	cool-off duration	t_c	5.2	sec

3.2 Tissue Material Combinations

The 4 different material combinations used are (Water, Brain), (Water, Blood), (Fat, Muscle), (Fat, Liver). The various KZK and bio-heat solver parameters are listed in tables below. Almost all the values used were taken from the ITIS Foundation tissue properties database, url: <https://itis.swiss/virtual-population/tissue-properties/database/database-summary>.

Note: The non-linearity parameter β is derived using the B/A value from the database mentioned above and calculated using Eq. 3.1.

$$\beta = 1 + \frac{B}{2A} \quad (3.1)$$

Water and Brain

The KZK and BHT parameters used are shown in Table 3.3.

Examples of intensity and temperature maps generated are shown in Figure 3.1 and Figure 3.2.

Table 3.3: Water-Brain Parameters

	Parameter	symbol	value	unit
Material 1 (Water)	small-signal speed sound	c_1	1482	m/s
	mass density	ρ_1	1000	kg/m^3
	absorption at 1 MHz	α_1	0.217	dB/m
	Exponent of absorption vs. frequency curve	η_1	2	—

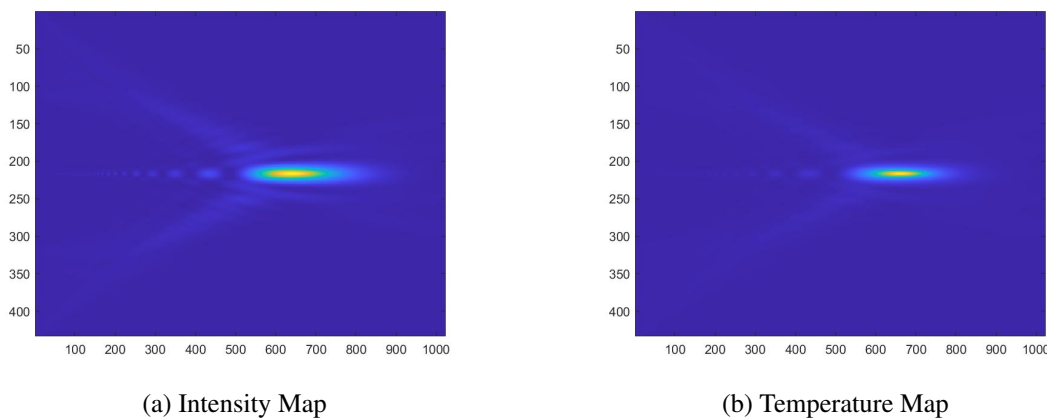

Figure 3.8: Fat liver - Intensity Map (a) and Temperature Map (b) with frequency 1.0MHz and power 280W .

3.3 Post-processing

The images generated by the HIFU simulator in MATLAB are of size 875×656 and have the x, y axis from the *imagesc* method. The white space around the image will also affect the overall quality of how the GAN will react to the input data and hence must be removed. The *imcrop* method from MATLAB is used to remove the extra white space and axis with minimum loss of features from the intensity and temperature maps. The cropped images are also resized to 512×512 to maintain the radix-2 nature of input data for the GAN to avoid unnecessary padding. The entire numerical simulation process can be summed up in Figure 3.9.

Figure 3.9: Flowchart of post-processing of the intensity and temperature maps.

An example of the resized image is given in Figure 3.10.

Figure 3.10: Fat-Muscle intensity map with frequency 0.6 MHz and power 300 W after post-processing.

Chapter 4

Results

The data set generated from the HIFU simulator was used as input to the generative adversarial network. For the intensity and temperature maps, the frequency had a range of 0.3 to 3 MHz while power was in the range of 80 to 500 W. The MATLAB simulation and PyTorch based network were run on desktop grade hardware with 32 GB of DDR4 RAM, Intel i7-7700HQ quad core and NVidia GeForce GTX 1060 Max-Q GPU. Table 4.1 contains the specifications of the hardware used.

Table 4.1: Computer Hardware Specifications

Hardware	Specification
CPU	Intel i7-7700HQ @ 2.8 GHz
Memory	32 GB DDR4 RAM
GPU	NVidia GeForce GTX 1060 Max-Q
Operating System	Microsoft Windows 10
System Type	x64

This chapter primarily discusses the training and testing of the generative adversarial network along with graphical representations of various loss measurements made between the generated temperature map and ground truth.

4.1 Training

The process of training in machine learning involves the learning process of the network and the fitting of parameters such as the weights. The HIFU data set comprised of 1000 intensity and temperature maps is randomly split into 80% for training and 20% for testing. An iterative approach with the training data set being run through the generator and discriminator for 400 epochs with a batch size of 3 on the CUDA-enabled GPU. The computation of each batch took roughly a second due to the GPU being used as the torch device.

The input intensity maps and ground truth temperature maps are loaded along with the models to begin the training. The generator follows the U-net architecture described earlier, and the discriminator provides a real or fake probability corresponding to how well the generator predicted the temperature. A log file is created to keep track of the generator and discriminator loss which is updated every epoch. Adam optimization [21] is also applied to the generator and discriminator parameters with a learning rate of 0.0002, first moment coefficient β_1 equal to 0.5, second moment coefficient β_2 equal to 0.999, and weight decay of 0.00001. Batch normalization [22] and non-linear activation functions (ReLU) are used in the convolution layers of the generator and discriminator models for feature extraction. On the hardware specifications mentioned previously, training took almost three days which shows the need for higher performance computers.

The generator and discriminator loss graphs are shown in Figure 4.1.

Figure 4.1: Plots of Generator Loss (a) and Discriminator Loss (b)

4.2 Testing

After each epoch, the testing data set of 20% images is used to see how well the network can predict based on its best training model. The Mean Absolute Error (MAE) and Mean Squared Error (MSE) between the predicted temperature map and the ground truth are also calculated accordingly. The test log file stores these errors for plotting of the graphs.

Some results of the predicted temperature maps are shown in Figure 4.2 and Figure 4.3 along with the actual temperature map.

Figure 4.2: Fat liver - Actual Temperature Map (a) and Predicted Temperature Map (b) with frequency 1.5 MHz and power 500 W.

Figure 4.3: Water Brain - Actual Temperature Map (a) and Predicted Temperature Map (b) with frequency 0.6 MHz and power 200 W.

The MAE and MSE graphs are shown in Figure 4.4.

(a) MAE vs. Epochs

(b) MSE vs. Epochs

Figure 4.4: Plots of Mean Average Error (a) and Mean Squared Error (b)

The MSE error is large, which may be due to not enough training or a small data set. The initial results with just a simple GAN are still quite positive as there is a prediction of heating focal regions in most fake generated temperature maps. For tissue combinations where there is a line separating the two tissues, the partition of heating regions is also seen in a few predicted temperature maps.

Chapter 5

Conclusion

With the current lack of real-time thermal monitoring, ultrasound temperature estimations seem to hold significant promise with their low cost, portability, and high-quality images. The use of generative adversarial networks also holds great promise in the search for clinical-based therapy, where regulation of heating is crucial.

Chapter 1 gave an introduction to medical imaging with a focus on high-intensity focused ultrasound. Lesion and ablation formation were discussed with the need to regulate heating in order to destroy only cancerous cells keeping nearby healthy cells intact. The rise of neural networks and how they can be used for medical imaging was also discussed with an emphasis on the possibilities for generative adversarial networks for the task of ultrasound temperature estimation.

Chapter 2 discussed the theory and methods behind the MATLAB-based HIFU simulator and PyTorch-based generative adversarial network being used. The HIFU simulator was used to generate intensity and temperature maps for 4 different tissue combinations. The simulator is comprised of an acoustic model and a thermal model. Due to the non-linear effects of an ultrasound wave, the KZK equation is used to solve non-linear acoustics. The bio-heat transfer equation governs the thermal effects when a tissue is heated. The solution to the equation is an estimate of the temperature profile in the localized region. The generative adversarial network consists of two adversaries, namely, the generator and the discriminator. The generator comprises of a U-net architecture that provides for the temperature map prediction, whereas the discriminator acts as a binary classifier on how real or fake the prediction is.

Chapter 3 discusses the numerical simulation involved with the various parameters involved across the 4 tissue combinations of (Water, Brain), (Water, Blood), (Fat, Muscle), (Fat, Liver). 250 intensity and temperature maps per tissue combination are generated in the HIFU simulator resulting in a data set comprised of 1000 intensity and temperature maps. Since the maps generated contain unnecessary white spaces and axis, post-processing needs to be done in order to make them best suited for training in the generative adversarial networks. MATLAB-based image-processing

methods are used to achieve this.

Chapter 4 discusses the computer specifications being used and the generative adversarial network training and testing for ultrasound temperature estimation. The data set is randomly split into an 80 – 20 ratio for training and testing, respectively. The MSE and MAE metrics are used for error analysis and the results generated are promising. The section concludes with some examples of predicted temperature maps, along with the ground truths and error analysis plots.

5.1 Impact

The generative adversarial network built for the purpose of ultrasound temperature estimation allows for real-time monitoring while performing clinical thermotherapy. Each test case took less than a second to predict the corresponding temperature map. If the temperature at a focal point goes beyond a particular requirement in clinical thermotherapy, it could damage nearby healthy tissues. With a high-performance neural network such as the GAN, real-time temperature regulation is possible, as this thesis's work would suggest.

5.2 Future Work

While the use of a simple generative adversarial network is only one step towards the process of ultrasound temperature estimation, other more advanced GANs such as those in [14] could also be implemented to analyze and study the predictions made.

In order to achieve better results, more intensity and temperature maps across a more extensive range of frequencies and power need to be generated as well to allow for better training. The HIFU simulator by [17] can also be used for more tissue combinations with their respective parameters. The same author also builds a high-intensity therapeutic ultrasound (HITU) simulator, which could be studied and experimented with for the data set generation.

Venturing into better architectures and optimization techniques for the GAN would be an optimal move forward. Ultrasound temperature estimation using generative adversarial networks has provided positive results in its first iteration and could be the solution to real-time thermal monitoring.

ACADEMIC VITA

MUAYYAD SAFRI

safrimuayyad@gmail.com

EDUCATION

The Pennsylvania State University
College of Engineering, Schreyer Honors College
B.S. Computer Engineering, Minor in Mathematics

University Park, PA
Expected Graduation May 2021

TECHNICAL EXPERIENCE

Software Engineering Internship at Arista Networks rescinded due to COVID-19

Ultrasound in Imaging and Therapy (UIT) Lab

Undergraduate Research

University Park, PA

May 2020 – present

- Working towards temperature estimation in ultrasound tissue images using computer vision and deep learning techniques
- Currently building a physics-based model and generative adversarial network (GAN) to generate the temperature maps
- Using TensorFlow and PyTorch frameworks along with MATLAB to achieve a working simulation

Siemens

Capstone Design Project

University Park, PA

August 2020 – December 2020

- Developed a Bluetooth program to securely connect the IOT2040 to a Bluetooth LR100 using an Arduino microcontroller
- Worked on the storage subsystem that utilized the EEPROM to allow for storage of sensor data in a database table
- After receiving and appropriately storing device information in the IOT2040, prepared data to be sent to the MindSphere cloud

Emerson Electric Co.

Software Development Intern – Project ROBOT

Pune, India

June 2019 – July 2019

- Developed a centralized web based system to track booking data, delayed orders and generate customized excel reports
- Used the Django web framework following the Model Template View (MTV) architecture to build the web application
- Wrote Python scripts and created HTML templates to allow order entry and editing for multiple business units of Emerson
- Ajax was used to search existing orders in the SQLite3 database and JavaScript enabled conversion of tables to excel sheets

ACADEMIC PROJECTS

Dynamic Storage Allocator

C - based project

University Park, PA

January 2020 – February 2020

- Designed a version of malloc, free and realloc functions using a segregated free list design with First Fit and LIFO policies
- Implemented my own heap consistency checker as a debugging tool to check for multiple invariants and block corruptions

5-stage Pipelined CPU

VHDL project

University Park, PA

March 2019 – May 2019

- Created a Verilog based 5-stage 32-bit pipelined CPU to handle multiple instructions of R, I and J format
- Forwarding unit included to handle data hazards, reduce stalls and improve performance; research as part of honors credit

Draw Assist

HackPSU

University Park, PA

March 2019

- Best overall hack among 90 teams and over 1000 participants, article about the project was published in Penn State news
- Used Google's speech-to-text API to convert audio input into G-code written in python scripts
- Programmed the CNC controller to write the exact text spoken by a user in a unique font
- Created a simple PyQt GUI for basic commands such as print, record and clear to be displayed using DragonBoard circuitry

LEADERSHIP AND VOLUNTEERING EXPERIENCE

CSE Learning Assistant

CMPEN331 – Computer Organization and Design

University Park, PA

May, 2019 – December 2019, May 2020 – Present

- Conduct weekly office hours to help students understand key concepts of computer architecture and its components
- Grade Verilog and MIPS based labs/projects and provide feedback to students

THON 2019

OPP Committee – Member of Sgro with the flow

University Park, PA

October 2018 – February 2019

- Part of OPPerations to ensure BJC is clean, maintained and running efficiently prior to, during, and after THON weekend
- Gift Card Initiative (GCI) Coordinator – collect gift cards from various outlets to raise sums for the OPP committee

SKILLS

- Object Oriented and Data Structures programming in C++, Python and Java; Systems programming experience in C
- Machine Learning and neural networks experience with NumPy, Scikit-learn, Tensorflow, PyTorch and MATLAB
- Multiple project experiences with Xilinx for FPGAs, Verilog, Arduino UNO circuitry, Multisim and 3D printing
